

**ENCRYPTION AND DECRYPTION
WITH ENDURANCE TO CRYPTANALYSIS METHOD**

Background of the Invention

5 1. Field of the Invention

The present invention relates to encryption and decryption with endurance to cryptanalysis method.

10 2. Description of the Related Art

10 A conventional encrypting apparatus is composed of an input unit, a storage unit, an encryption processing unit and an output unit. A plaintext is supplied to the encryption processing unit from the input unit. The
15 encryption processing unit always carries out an encrypting operation in accordance with a predetermined processing procedure at each of a plurality of processing stages of the encrypting operation to generate a ciphertext, while storing
20 an intermediate data at each processing stage in the storage unit. The intermediate data is required at the next processing stage of the encrypting operation. The generated ciphertext is output from the output unit. In this case, the
25 time period from the time when the encrypting operation is started to the time when a specific intermediate stage of the encrypting operation is

000240" STESS60

started is approximately constant.

It should be noted that a method of implementing cipher algorithm is described in detail in "Applied Cryptography" by Bruce Schneier
5 (John Wiley & Sons, Inc., 1996, ISBN 0-471-11709-9, pp.623-673".

In the above mentioned conventional example of the encrypting apparatus, cryptanalysis methods such as a simple power analysis and a
10 differential power analysis are effective. The simple power analysis and the differential power analysis uses the feature that the consumption power becomes larger when a data held in a
15 semiconductor device is changed, compared with a case that the held data is not changed. In the cryptanalysis method, the power consumption of the encrypting apparatus is measured at a plurality of timings while the encrypting operation of a plaintext is carried out to
20 specify secret information such as a secret key (an encrypt key) in the encrypting apparatus.

The following two conditions must be met for the purpose that the simple power analysis or the differential power analysis functions
25 effectively. That is, the first condition is that an executed stage of the encrypting operation can be specified each time the power consumption is

000240"STHES560

measured. The second condition is that the measured value of the power consumption at each stage conspicuously reflects the calculation result of the encrypting operation carried out in
5 the encrypting apparatus.

When the above-mentioned two conditions have been met in the conventional encrypting apparatus, the simple power analysis or the differential power analysis functions effectively
10 to make the decryption possible. This is applied to a decrypting apparatus and an encrypting and decrypting apparatus in the same manner.

A method of encrypting data is disclosed in Japanese Laid Open Patent Application (JP-A-
15 Heisei 9-230786) and Japanese Laid Open Patent Application (JP-A-Heisei 8-504067) in relation to the above conventional technique. In these references, differential decipherment and linear decipherment are prevented. The intermediate
20 results of the encrypting operation are changed without depending on the random numbers and an encrypt key is changed in dependence on the random numbers.

Also, an improved secretness in the
25 encrypting communication device is disclosed in Japanese Laid Open Patent Application (JP-A-Heisei 8-504067). In this reference, when power

000240-5THES550
09553415-042000

is turned off, key information stored in a volatile memory in the encrypting apparatus is dynamically erased, and the same key information is re-loaded when the supply of power is resumed.

5 Even if these techniques are combined, it is very difficult to remove the dependence of the finally outputted ciphertext on the random numbers.

10 In conjunction with the above description, a verification method is disclosed in Japanese Laid Open Patent Application (JP-A-Heisei 10-210023). In this reference, the first station and the second station stores common secret information K_a ($K'a$) in storage sections (13) and 15 (43) at each station. The first station transmits to the second station, the user information (I_a) indicating that the first station is a first station. One of the first and second stations generates and transmits random numbers r to the 20 other station. The first station generates first verification information using the random numbers, secret information and predetermined algorithm, and transmits it to the second station. The second station generates second 25 verification information using the random numbers, secret information and the predetermined algorithm. The second station compares the first

000240" STESS56
09553415-042000

verification information and the second verification information and determines authority of the first station based on whether both are the same.

5 Also, a method of generating a hash value is disclosed in Japanese Laid Open Patent Application (JP-A-Heisei 10-340048). In this reference, when a message is given, divisional data of the message are inputted and monomorphism
10 expansion processing is carried out to output a data which is longer than the divisional data. Also, a hash value is generated by a hash function which contains a multiplying process and circulated shifting process. In this way, a hash
15 value and a key or a ciphertext with a high data distortion are quickly generated.

Also, a computer supporting exchanging method of an encrypt key between a user computer unit U and a network computer unit N is disclosed
20 in Japanese Laid Open Patent Application (JP-A-Heisei 10-510692). In this reference, the length of a message to be transmitted is reduced. The first intermediate key and the second intermediate key are generated in dependence on
25 the random numbers. In a network computer unit and a user computer unit, by carrying out the exclusion OR calculation of the first

000240" STESS60
09553415-042000

intermediate key and the second intermediate key for every bit, a session key is calculated. This key is not absolutely transmitted in a plaintext. For example, a predetermined function such as a symmetrical encrypting function, a hash function and a one-way function is used. Thus, the network computer unit and the user computer unit are verified each other.

10

Summary of the Invention

Therefore, an object of the present invention is to provide an encrypting and/or decrypting apparatus which has endurance to cryptanalysis methods such as a simple power analysis and a differential power analysis.

Another object of the present invention is to provide an encrypting and/or decrypting apparatus in which the processing state of an encrypting and/or decrypting operation is changed based on random number.

Still another object of the present invention is to provide an encrypting and/or decrypting apparatus in which intermediate data of an encrypting and/or decrypting operation is changed based on random number.

Yet still another object of the present invention is to provide an encrypting and/or

09553415-042000

decrypting apparatus in which an encrypting and/or decrypting procedure of an encrypting and/or decrypting operation is changed based on random number.

5 It is an object of the present invention is to provide an encrypting and/or decrypting apparatus in which a delay time is inserted into an encrypting and/or decrypting operation based on random number.

10 Another object of the present invention is to provide an encrypting and/or decrypting method in which the processing state of an encrypting and/or decrypting operation is changed based on random number.

15 Still another object of the present invention is to provide a recording medium in which a program for the above encrypting and/or decrypting method is stored.

In order to achieve a first aspect of the present invention, an encrypting apparatus includes an encrypting operation section, a determining section and a control section. The encrypting operation section carries out an encrypting operation to a plaintext using intermediate data at each of a plurality of encrypting stages of the encrypting operation to produce a ciphertext. The encrypting operation

section outputs encrypting stage data indicating an encrypting state at each of the plurality of processing stages. The determining section determines whether the encrypting operation at a
5 next encrypting stage should be changed, based on the encrypting stage data at a current encrypting stage from the encrypting operation section. The control section changing the encrypting operation at the next encrypting stage when it is
10 determined that the encrypting operation at the next encrypting stage should be changed.

The determining section may determine whether the intermediate data at the next encrypting stage of the encrypting operation
15 should be changed depending on at least a random number, based on the encrypting stage data at the current encrypting stage from the encrypting operation section. The encrypting stage data includes the intermediate data at the next
20 encrypting stage. In this case, the control section changes the intermediate data at the next encrypting stage depending on the random number. Also, the control section may change the intermediate data at the next encrypting stage
25 depending on the plaintext or a data dependent on the plaintext in place of the random number.

Also, the determining section may determine

000240"ST4E5560

whether an encrypting procedure at the next
encrypting stage of the encrypting operation
should be changed depending on at least a random
number, based on the encrypting stage data at the
5 current encrypting stage from the encrypting
operation section. In this case, the control
section changes the encrypting procedure at the
next encrypting stage of the encrypting operation
depending on the random number. Also, the control
10 section may change the encrypting procedure at
the next encrypting stage of the encrypting
operation depending on the plaintext or a data
dependent on the plaintext in place of the random
number.

15 Also, the determining section may determine
whether the encrypting operation at the next
encrypting stage should be changed depending on
at least a random number, based on the encrypting
stage data at the current encrypting stage from
20 the encrypting operation section. In this case,
the control section inserts a delay time in the
encrypting operation at the next encrypting stage
depending on the random number. Also, the control
section may insert the delay time in the
25 encrypting operation at the next encrypting stage
depending on the plaintext or a data dependent on
the plaintext in place of the random number.

000240 STESS60
09553415 042000

Here, the determining section may determine whether the intermediate data at the next decrypting stage of the decrypting operation should be changed depending on at least a random number, based on the decrypting stage data at the current decrypting stage from the decrypting operation section. Also, the stage data includes

Here, the determining section may determine whether the intermediate data at the next decrypting stage of the decrypting operation should be changed depending on at least a random number, based on the decrypting stage data at the current decrypting stage from the decrypting operation section. Also, the stage data includes

the intermediate data for the next decrypting stage. In this case, the control section may change the intermediate data at the next decrypting stage depending on the random number.

- 5 Also, the control section may change the intermediate data at the next decrypting stage depending on the ciphertext or a data dependent on the ciphertext in place of the random number.

- Also, the determining section determines
- 10 whether a decrypting procedure at the next decrypting stage of the decrypting operation should be changed depending on at least a random number, based on the stage data at the current decrypting stage from the decrypting operation
- 15 section. In this case, the control section may change the decrypting procedure at the next decrypting stage of the decrypting operation depending on the random number. In this case, the control section may change the decrypting
- 20 procedure at the next decrypting stage of the decrypting operation depending on the ciphertext or a data dependent on the ciphertext in place of the random number.

- Also, the determining section determines
- 25 whether the decrypting operation at the next decrypting stage should be changed depending on at least a random number, based on the stage data

000240-042000

at the current decrypting stage from the
decrypting operation section. In this case, the
control section inserts a delay time in the
decrypting operation at the next decrypting stage
5 depending on the random number. Also, the control
section may insert the delay time in the
decrypting operation at the next decrypting stage
depending on the ciphertext or a data dependent
on the ciphertext in place of the random number.

10 In order to achieve a third aspect of the
present invention, an encrypting and decrypting
apparatus includes an encrypting and decrypting
operation, a determining section and a control
section. The encrypting and decrypting operation
15 section determines whether an inputted
instruction is an encrypt instruction or a
decrypt instruction, carries out an encrypting
operation to an inputted text in response to the
encrypt instruction using first intermediate data
20 at each of a plurality of encrypting stages of
the encrypting operation to produce a ciphertext,
and carries out a decrypting operation to the
inputted text in response to the decrypt
instruction using second intermediate data at at
25 each of a plurality of decrypting stages of the
decrypting operation to produce a second
plaintext. The encrypting and decrypting

000240" ST4E5560

operation section outputs encrypting stage data indicating an encrypting state at each of the plurality of encrypting stages and outputs decrypting stage data indicating a decrypting state at each of the plurality of decrypting stages. The determining section determines whether the encrypting operation at a next encrypting stage should be changed, based on the encrypting stage data at a current encrypting stage from the encrypting and decrypting operation section, and determines whether the decrypting operation at a next decrypting stage should be changed, based on the decrypting stage data at a current decrypting stage from the encrypting and decrypting operation section. The control section changes the encrypting operation at the next encrypting stage when it is determined that the encrypting operation at the next encrypting stage should be changed, and changes the decrypting operation at the next decrypting stage when it is determined that the decrypting operation at the next decrypting stage should be changed.

Here, the determining section may determine whether the first intermediate data at the next encrypting stage of the encrypting operation should be changed depending on at least a first

000240" 5745550

random number, based on the encrypting stage data at the current encrypting stage from the encrypting and decrypting operation section, and determine whether the second intermediate data at the next decrypting stage of the decrypting operation should be changed depending on at least a second random number, based on the decrypting stage data at the current decrypting stage from the encrypting and decrypting operation section.

10 The encrypting stage data includes the first intermediate data at the next encrypting stage and the decrypting stage data includes the second intermediate data for the next decrypting stage. In this case, the control section changes the

15 first intermediate data at the next encrypting stage depending on the first random number and changes the second intermediate data at the next decrypting stage depending on the second random number. Also, the control section may change the

20 first intermediate data at the next encrypting stage depending on the inputted text or a data dependent on the inputted text in place of the first random number, and change the second intermediate data at the next decrypting stage

25 depending on the inputted text or the data dependent on the inputted text in place of the second random number.

Also, the determining section may determine whether an encrypting procedure at the next encrypting stage of the encrypting operation should be changed depending on at least a first random number, based on the encrypting stage data at the current encrypting stage from the encrypting and decrypting operation section, and determine whether a decrypting procedure at the next decrypting stage of the decrypting operation should be changed depending on at least a second random number, based on the decrypting stage data at the current decrypting stage from the encrypting and decrypting operation section. In this case, the control section changes the encrypting procedure at the next encrypting stage of the encrypting operation depending on the first random number and changes the decrypting procedure at the next decrypting stage of the decrypting operation depending on the second random number. Also, the control section may change the encrypting procedure at the next encrypting stage of the encrypting operation depending on the inputted text or a data dependent on the inputted text in place of the first random number, and change the decrypting procedure at the next decrypting stage of the decrypting operation depending on the inputted

000020" 512550

Also, the determining section may determine whether the encrypting operation at the next

Also, the control section may insert the first delay time in the encrypting operation at the next encrypting stage depending on the inputted text or a data dependent on the inputted text in place of the first random number, and insert the second delay time in the decrypting operation at the next decrypting stage depending on the

inputted text or the data dependent on the
inputted text in place of the second random
number.

In order to achieve a fourth aspect of the
5 present invention, an encrypting method includes
(a) determining whether an encrypting operation
at a current encrypting stage should be changed,
based on encrypting stage data at a previous
encrypting stage, the encrypting stage data at
10 the previous encrypting stage indicating an
encrypting state at the previous encrypting
stage; (b) changing the encrypting operation at
the current encrypting stage when it is
determined that the encrypting operation at the
15 current encrypting stage should be changed; (c)
carrying out the encrypting operation at the
current encrypting stage to a plaintext using
intermediate data at the current encrypting
stage; and (d) executing the steps (a) to (c) to
20 each of a plurality of the encrypting stages of
the encrypting operation to produce a ciphertext.

Here, the determining may include:
determining whether the intermediate data at the
current encrypting stage of the encrypting
25 operation should be changed depending on at least
a random number, based on the encrypting stage
data at the previous encrypting stage. The

000024015145560

5

15

25

the encrypting stage data at the previous encrypting stage. Also, the changing may include: inserting a delay time in the encrypting operation at the current encrypting stage

5 depending on the random number. In this case, the changing may include: inserting the delay time in the encrypting operation at the current encrypting stage depending on the plaintext or a data dependent on the plaintext in place of the
10 random number.

Also, in order to a fifth aspect of the present invention, a decrypting method includes: (a) determining whether a decrypting operation at a current decrypting stage should be changed,
15 based on decrypting stage data at a previous decrypting stage, the decrypting stage data at the previous decrypting stage indicating an decrypting state at each of the plurality of processing stages; (b) changing the decrypting
20 operation at the current decrypting stage when it is determined that the decrypting operation at the next decrypting stage should be changed; (c) carrying out the decrypting operation at the current decrypting stage to a ciphertext using
25 intermediate data at the current decrypting stage; and (d) executing the steps (a) to (c) to each of a plurality of decrypting stages to

0000240" 5145560

Here, the determining may include:

operation should be changed depending on at least a random number, based on the decrypting stage data at the previous decrypting stage. Also, the stage data includes the intermediate data at the current decrypting stage. In this case, the

changing may include: changing the intermediate data at the current decrypting stage depending on the random number. Also, the changing may include: changing the intermediate data at the current decrypting stage depending on the ciphertext or a data dependent on the ciphertext in place of the random number.

determining whether a decrypting procedure at the
current decrypting stage of the decrypting

operation should be changed depending on at least a random number, based on the decrypting stage data at the previous decrypting stage. In this case, the changing may include: changing the decrypting procedure at the current decrypting stage of the decrypting operation depending on the random number. Also, the changing includes: changing the decrypting procedure at the current

decrypting stage of the decrypting operation depending on the ciphertext or a data dependent on the ciphertext in place of the random number.

Also, the determining may include:

5 determining whether the decrypting operation at the current decrypting stage should be changed depending on at least a random number, based on the decrypting stage data at the previous decrypting stage. In this case, the changing may include: inserting a delay time in the decrypting operation at the current decrypting stage depending on the random number. Also, the changing may include: inserting the delay time in the decrypting operation at the current

10 decrypting stage depending on the ciphertext or a data dependent on the ciphertext in place of the random number.

In order to achieve a sixth aspect of the present invention, an encrypting and decrypting method include: (a) determining whether an inputted instruction is an encrypt instruction or a decrypt instruction; (b) determining whether the encrypting operation to a text at a current encrypting stage of an encrypting operation should be changed, based on the encrypting stage data at a previous encrypting stage, the encrypting stage data at the current encrypting

stage indicating an encrypting state at the current encrypting stage; (c) changing the encrypting operation to the text at the current encrypting stage when it is determined that the encrypting operation to the text at the current encrypting stage should be changed; (d) carrying out the encrypting operation to the text using first intermediate data at current encrypting stage of the encrypting operation; (e) executing the steps (b) to (d) to each of a plurality of encrypting stages of the encrypting operation to the text in response to the encrypt instruction to produce a ciphertext; (f) determining whether the decrypting operation to the text at a current decrypting stage should be changed, based on the decrypting stage data at a previous decrypting stage, the decrypting stage data at the current decrypting stage indicating an decrypting state at the current decrypting stage; (g) changing the decrypting operation to the text at the current decrypting stage when it is determined that the decrypting operation to the text at the current decrypting stage should be changed; (h) carrying out the decrypting operation to the text to a second ciphertext using second intermediate data at the current decrypting stage; and (i) executing the steps (f) to (h) for each of a

plurality of decrypting stages of the encrypting operation to the text in response to the decrypt instruction to produce a plaintext.

Here, the (b) determining may include:

5 determining whether the first intermediate data
at the current encrypting stage of the encrypting
operation should be changed depending on at least
a first random number, based on the encrypting
stage data at the previous encrypting stage. The
10 (f) determining may include: determining whether
the second intermediate data at the current
decrypting stage of the decrypting operation
should be changed depending on at least a second
random number, based on the decrypting stage data
15 at the previous decrypting stage. The encrypting
stage data includes the first intermediate data
at the current encrypting stage and the
decrypting stage data includes the second
intermediate data for the current decrypting
20 stage. In this case, the (c) changing may
include: changing the first intermediate data at
the current encrypting stage depending on the
first random number. Also, the (g) changing may
include: changing the second intermediate data at
25 the current decrypting stage depending on the
second random number. In this case, the (c)
changing may include: changing the first

intermediate data at the current encrypting stage depending on the text or a data dependent on the text in place of the first random number. Also, the (g) changing may include: changing the second
5 intermediate data at the current decrypting stage depending on the text or the data dependent on the text in place of the second random number.

Also, the (b) determining may include:
determining whether an encrypting procedure at
10 the current encrypting stage of the encrypting operation should be changed depending on at least a first random number, based on the encrypting stage data at the previous encrypting stage, and the (f) determining may include: determining
15 whether a decrypting procedure at the current decrypting stage of the decrypting operation should be changed depending on at least a second random number, based on the decrypting stage data at the previous decrypting stage. In this case,
20 the (c) changing may include: changing the encrypting procedure at the current encrypting stage of the encrypting operation depending on the first random number, and the (g) changing may include: changing the decrypting procedure at the
25 current decrypting stage of the decrypting operation depending on the second random number. Also, the (c) changing may include: changing the

0000240" STE 5560

encrypting procedure at the current encrypting stage of the encrypting operation depending on the text or a data dependent on the text in place of the first random number, and the (g) changing
5 may include: changing the decrypting procedure at the current decrypting stage of the decrypting operation depending on the text or the data dependent on the text in place of the second random number.

10 Also, the (b) determining may include: determining whether the encrypting operation at the current encrypting stage should be changed depending on at least a first random number, based on the encrypting stage data at the
15 previous encrypting stage, and the (f) determining may include: determining whether the decrypting operation at the current decrypting stage should be changed depending on at least a second random number, based on the decrypting
20 stage data at the previous decrypting stage. In this case, the (c) changing may include: inserting a first delay time in the encrypting operation at the current encrypting stage depending on the first random number, and the (g)
25 changing may include: inserting a second delay time in the decrypting operation at the current decrypting stage depending on the second random

09553415-042000

number. Also, the (c) changing may include:
inserting the first delay time in the encrypting
operation at the current encrypting stage
depending on the text or a data dependent on the
5 text in place of the first random number, and the
(f) changing may include: inserting the second
delay time in the decrypting operation at the
current decrypting stage depending on the text or
the data dependent on the text in place of the
10 second random number.

In order to achieve a seventh aspect of the
present invention, a recording medium stores a
problem for an encrypting method. The encrypting
method includes: (a) determining whether an
15 encrypting operation at a current encrypting
stage should be changed, based on encrypting
stage data at a previous encrypting stage, the
encrypting stage data at the previous encrypting
stage indicating an encrypting state at the
20 previous encrypting stage; (b) changing the
encrypting operation at the current encrypting
stage when it is determined that the encrypting
operation at the current encrypting stage should
be changed; (c) carrying out the encrypting
25 operation at the current encrypting stage to a
plaintext using intermediate data at the current
encrypting stage; and (d) executing the steps (a)

09553415.042000

to (c) to each of a plurality of the encrypting stages of the encrypting operation to produce a ciphertext.

In order to achieve an eighth aspect of the present invention, a recording medium stores a program for a decrypting method. The decrypting method includes: (a) determining whether a decrypting operation at a current decrypting stage should be changed, based on decrypting stage data at a previous decrypting stage, the decrypting stage data at the previous decrypting stage indicating an decrypting state at each of the plurality of processing stages; (b) changing the decrypting operation at the current decrypting stage when it is determined that the decrypting operation at the next decrypting stage should be changed; (c) carrying out the decrypting operation at the current decrypting stage to a ciphertext using intermediate data at the current decrypting stage; and (d) executing the steps (a) to (c) to each of a plurality of decrypting stages to produce a plaintext.

In order to achieve a ninth aspect of the present invention, a recording medium stores a problem for an encrypting and decrypting method. The encrypting and decrypting method includes: (a) determining whether an inputted instruction

09553415.042000

is an encrypt instruction or a decrypt instruction; (b) determining whether the encrypting operation to a text at a current encrypting stage of an encrypting operation

5 should be changed, based on the encrypting stage data at a previous encrypting stage, the encrypting stage data at the current encrypting stage indicating an encrypting state at the current encrypting stage; (c) changing the

10 encrypting operation to a text at the current encrypting stage when it is determined that the encrypting operation to a text at the current encrypting stage should be changed; (d) carrying out the encrypting operation to to a text using

15 first intermediate data at current encrypting stage of the encrypting operation; (e) executing the steps (b) to (d) for each of a plurality of encrypting stages of the encrypting operation to the text in response to the encrypt instruction

20 to produce a ciphertext; (f) determining whether the decrypting operation to the text at a current decrypting stage should be changed, based on the decrypting stage data at a previous decrypting stage, the decrypting stage data at the current

25 decrypting stage indicating an decrypting state at the current decrypting stage; (g) changing the decrypting operation to the text at the current

09553415.042000

decrypting stage when it is determined that the
decrypting operation to the text at the current
decrypting stage should be changed; (h) carrying
out the decrypting operation to the text to a
5 second ciphertext using second intermediate data
at the current decrypting stage; and (i)
executing the steps (f) to (h) for each of a
plurality of decrypting stages of the encrypting
operation to the text in response to the decrypt
10 instruction to produce a plaintext.

10 **Description of the Preferred Embodiments**

Next, an encrypting and/or decrypting
apparatus of the present invention will be
described below in detail with reference to the
attached drawings.

15

(1) First embodiment

Fig. 1 is a block diagram showing the
structure of an encrypting apparatus according to
the first embodiment of the present invention.

20

Referring to Fig. 1, the encrypting
apparatus in the first embodiment is composed of
an input unit 110, an encryption processing unit
120, a storage unit 130, a random number
generating unit 140 and an output unit 150. The

25

encryption processing unit 120 is composed of an
encrypting operation section 121, a random number
dependence determining section 122 and an

0000240" 514E560

intermediate data control section 123.

The input unit 110 supplies a plaintext as the object of an encrypting operation to the encryption processing unit 120.

5 The encryption processing unit 120 encrypts the plaintext supplied from the input unit 110 based on random numbers supplied from the random number generating unit 140 using an encrypt key stored in the encryption processing unit 120 so
10 that a ciphertext is outputted from the output unit 150.

 The encrypting operation section 121 encrypts the plaintext supplied from the input unit 110 using the encrypt key stored in the
15 encrypting operation section 121. The encrypting operation is composed of plurality of processing stages. The encrypting operation section 121 informs the stage data indicating the processing state of the encrypting operation at each of the
20 plurality of stages during execution of the encrypting operation to the random number dependence determining section 122. Also, the encrypting operation section 121 stores
25 intermediate data at each processing stage during the encrypting operation in the intermediate data storage section 131 of the storage unit 130. The encrypting operation section 121 carries out the

00553415-042000

encrypting operation using the intermediate data changed in response to an intermediate data changing request from the intermediate data control section 123. Thus, the encrypting
5 operation is changed. The encrypting operation section 121 finally outputs a ciphertext obtained by encrypting the plaintext.

The random number dependence determining section 122 determines whether or not the
10 intermediate data changing request should be outputted to the intermediate data control section 123, based on stage data at each processing stage of the encrypting operation from the encrypting operation section 121. The random
15 number dependence determining section 122 outputs the intermediate data changing request to the intermediate data control section 123, when it is determined that intermediate data changing request should is outputted, that is, when the
20 current stage of the encrypting operation is determined to be the stage to which a random number dependent operation should be applied.

The intermediate data control section 123 sends a random number generating request in
25 response to the intermediate data changing request outputted from random number dependence determining section 122 to the random number

09553415.042000

generating unit 140. Then, the intermediate data control section 123 receives random numbers from the random number generating unit 140 and changes the intermediate data stored in the intermediate data storage section 131 based on the received random numbers. Hereinafter, this operation is referred to as a random number dependent intermediate data changing operation. It should be noted that the intermediate data control section 123 carries out the random number dependent intermediate data changing operation plural times to cancel the influence of the random numbers. Therefore, the final ciphertext does not depend on the random numbers outputted from the random number generating section 140. It should be noted that it is sufficient that at least a random number is generated, although the random numbers are generated in the first embodiment. This is applied to the following embodiments.

The intermediate data storage section 131 of the storage section 130 stores the intermediate data during the encrypting operation from the encryption processing unit 120. As described above, when the intermediate data changing request is outputted from the random number dependence determining section 122 to the

09553415 "042000

intermediate data control section 123, the intermediate data stored in the intermediate data storage section 131 is operated by the intermediate data control section 123.

5 The random number generating unit 140 generates the random numbers in response to the random number generating request from the encryption processing unit 120 to outputs to the encryption processing unit 120.

10 Fig. 2 is a flow chart showing the operation of the encrypting apparatus according to the first embodiment. The operation of the encrypting apparatus in the first embodiment will be described in detail with reference to Fig. 2.

15 First, the plaintext which should be encrypted is supplied from the input unit 110 to the encrypting operation section 121 in the encryption processing unit 120 (at a step A1 of Fig. 2).

20 The encrypting operation section 121 outputs the encrypting stage data at an encrypting stage of the encrypting operation by the encrypting operation section 121 to the random number dependence determining section 122
25 as the encrypting stage data at a previous encrypting stage.

The random number dependence determining

00553415 042000

section 122 determines based on the encrypting stage data at the previous encrypting stage, whether or not a current stage of the encrypting operation is the stage to change the intermediate data stored in the intermediate data storage section 131 in dependence on the random numbers. When the current stage is determined to be the stage which the intermediate data should be changed in dependence on the random numbers, the random number dependence determining section 122 outputs the intermediate data changing request to the intermediate data control section 123.

The intermediate data control section 123 determines whether or not the intermediate data changing request is outputted from the random number dependence determining section 122 (Step A2).

The intermediate data control section 123 receives the intermediate data changing request and sends the random number generating request to the random number generating unit 140, when it is determined at the step A2 that the intermediate data changing request is outputted. Also, the intermediate data control section 123 receives the random numbers outputted from the random number generating unit 140 based on the random number generating request (Step A3).

000240" STESSD
09553415 042000

0000240"5FHE5560

The intermediate data control section 123 receives the random numbers and carries out the random numbers dependent intermediate data changing operation to change the intermediate data stored in the intermediate data storage section 131 of the storage unit 130 based on the received random numbers (Step A4). The intermediate data is the data needed by the encrypting operation section 121 in the current encrypting stage of the encrypting operation. Through the change of the intermediate data, the encrypting operation at the current encrypting stage is changed.

The encryption operation section 121 executes the encrypting operation for a single stage, when the random number dependent intermediate data changing operation of the step A4 is ended, or when it is determined at the step A2 that the intermediate data changing request is not outputted (Step A5).

The encrypting operation section 121 determines whether or not the encrypting operation is ended, after the encrypting operation is executed for the single stage (Step A6). The encrypting operation section 121 outputs a ciphertext to the output unit 150, when it is determined at the step A6 that the encrypting

On the other hand, when the encrypting operation section 121 determines at the step A6 that the encrypting operation does not end, the control returns to the step A2 to continue the encrypting operation.

25 (2) Second embodiment

Fig. 3 is a block diagram showing the structure of the encrypting apparatus according

to the second embodiment of the present invention.

Referring to Fig. 3, the encrypting apparatus in the second embodiment is composed of
5 an input unit 310, an encryption processing unit 320, a storage unit 330, a random number generating unit 340 and an output unit 350. The encryption processing unit 320 is composed of an encrypting operation section 321, a random number
10 dependence determining section 322 and a conditional branch control unit 323.

The input unit 310 supplies a plaintext as the object of an encrypting operation to the encryption processing unit 320.

15 The encryption processing unit 320 encrypts the plaintext supplied from the input unit 310, based on the random numbers supplied from the random number generating unit 340 using an encrypt key stored in the encryption processing
20 unit 320, so that a ciphertext is outputted from the output unit 350.

The encrypting operation section 321 encrypts the plaintext supplied from the input unit 310 using the encrypt key stored in the
25 encrypting operation section 321. The encrypting operation section 321 outputs the encrypting stage data indicating the encrypting state at each

0000240" 5TH E5550

section 322 determines whether or not the conditional branch determining request should be outputted to the conditional branch control section 323, based on the encrypting stage data
5 from the encrypting operation section 321. The random number dependence determining section 322 outputs a conditional branch determining request to the conditional branch control section 324, when it is determined that the conditional branch
10 determining request should be outputted, that is, when the current encrypting stage of the encrypting operation is determined to be the stage to which a random number dependent operation should be applied.

15 The conditional branch control unit 323 sends the random number generating request to the random number generating unit 340, when the conditional branch determining request is supplied from the random number dependence
20 determining section 322. Then, the conditional branch control unit 323 acquires the random numbers. The conditional branch control unit 323 operates the random number dependent conditional branch determining operation based on the
25 acquired random numbers. That is, the conditional branch control unit 323 carries out the operation to determine the execution sequence of the

0000240" 51145560

plurality of encrypting operation procedures such that the output of the encrypting operation section 321 does not change even if the execution sequence is changed. Also, the conditional branch control unit 323 carries out to the operation to select one of the plurality of execution processing procedures such that the output of the encrypting operation section 321 does not change even if any of the plurality of processing procedures is carried out.

It should be noted that the conditional branch control unit 323 carries out the random number dependent conditional branch determining operation such that the output of the encrypting operation section 321 does not depend on the random numbers as mentioned above. Thus, the ciphertext as the final output does not depend on the random numbers which are outputted from the random number generating section 340.

The storage 330 is composed of an intermediate data storage section 331. The intermediate data storage section 331 stores the intermediate data to be held during the encrypting operation by the encryption processing unit 320.

The random number generating unit 340 generates the random numbers in response to the

09553415 "0420000

random number generating request from the encryption processing unit 320 to outputs to the encryption processing unit 320.

Fig. 4 is a flow chart showing the encrypting operation of the encrypting apparatus in the second embodiment. The encrypting operation is composed of a step B1 of supplying a plaintext, a step B2 of determining existence or non-existence of the conditional branch determining request, a step B3 of outputting the random numbers, a step B4 of carrying out the random number dependent conditional branch determining operation, a step B5 of carrying out one encrypting stage of the encrypting operation, a step B6 of determining the end of the encrypting operation, and a step B7 of outputting a ciphertext.

Next, the operation of the whole encrypting apparatus according to the second embodiment will be described in detail with reference to Fig. 4.

First, a plaintext which should be encrypted is supplied from the input unit 310 to the encrypting operation section 321 in the encryption processing unit 320 (at a step B1 of Fig. 4).

The encrypting operation section 321 outputs the encrypting stage data of the

0000240"15"042000

encrypting operation by the encrypting operation section 321 to the random number dependence determining section 322 as the encrypting stage data at a previous encrypting stage.

5 The random number dependence determining section 322 determines based on the encrypting stage data at the previous encrypting stage of the encrypting operation, whether or not the current encrypting stage of the encrypting
10 operation is the stage to determine a random number dependent conditional branch. When the current encrypting stage is determined to be the stage to determine the random number dependent conditional branch, the random number dependence
15 determining section 322 outputs the conditional branch determining request to the conditional branch control section 323.

 The conditional branch control section 323 determines whether or not the conditional branch
20 determining request is outputted from the random number dependence determining section 122 (Step B2).

 The conditional branch control section 323 receives the conditional branch determining
25 request, and sends the random number generating request to the random number generating unit 340, when it is determined at the step B2 that the

09553415 "042000

conditional branch determining request is
outputted. Also, the conditional branch control
section 323 receives the random numbers outputted
from the random number generating unit 340 based
5 on the conditional branch determining request
(Step B3).

The conditional branch control section 323
carries out the random number dependent
conditional branch determining operation based on
10 the random numbers, to select one to be actually
carried out of a plurality of processing
procedures which have the same output result in
dependence on the received random numbers (Step
B4).

15 The encryption operation section 321
carries out the encrypting operation for a single
stage when the random number dependent
conditional branch determining operation of the
step B4 is ended, or when it is determined at the
20 step B2 that the conditional branch determining
request is not outputted (Step B5).

The encrypting operation section 321
determines whether or not the encrypting
operation is ended, after the encrypting
25 operation is executed for the single stage (Step
B6).

The encrypting operation section 321

000240" STESS60
09553415 042000

outputs a ciphertext to the output unit 350, when it is determined at the step B6 that the encrypting operation is ended (Step B7). In this way, the whole processing ends.

5 On the other hand, when the encrypting operation section 321 determines at the step B6 that the encrypting operation does not end, the control returns to the step B2 to continue the encrypting operation.

10 In the second embodiment, the order and kind of the encrypting operation to be executed is changed based on the random numbers. Therefore, the encrypting operation procedures carried out in the encryption processing unit 320
15 are different depending on the random numbers. Thus, it is difficult to determine which of the encrypting operations corresponds to the change of the consumption power, even if the change of the consumption power is measured. Therefore, the
20 encrypting apparatus has the endurance to the cryptanalysis such as the simple power analysis and the power differential analysis.

(3) Third embodiment

25 Fig. 5 is a block diagram showing the structure of the encrypting apparatus according to the third embodiment of the present invention.

00553415-042000

Referring to Fig. 5, the encrypting apparatus in the third embodiment is composed of an input unit 510, an encryption processing unit 520, a storage unit 530, a random number
5 generating unit 540 and an output unit 550. The encryption processing unit 520 is composed of an encrypting operation section 521, a random number dependence determining section 522 and a delay control unit 523.

10 The input unit 510 supplies a plaintext as the object of an encrypting operation to the encryption processing unit 520.

The encryption processing unit 520 encrypts the plaintext supplied from the input unit 510,
15 based on the random numbers supplied from the random number generating unit 540 using an encrypt key stored in the encryption processing unit 520 so that a ciphertext is outputted from the output unit 550.

20 The encrypting operation section 521 encrypts the plaintext supplied from the input unit 510 using the encrypt key stored in the encrypting operation section 521. The encrypting operation section 521 outputs encrypting state
25 data indicating the encrypting state at each of a plurality of encrypting stages of the encrypting operation to the random number dependence

09553415 042000

determining section 522. The encrypting operation section 521 receives a random number dependent execution delay time changing request from the delay control unit 523. The encrypting operation
5 section 521 executes the encrypting operation while changing the encrypting state at each of the plurality of processing stages of the encrypting operation. The encrypting operation section 521 finally outputs the ciphertext
10 obtained by encrypting the plaintext.

It should be noted that the encrypting operation section 521 sends the current encrypting stage of the encrypting operation by the encrypting operation section 521 at each of
15 the plurality of encrypting stages during the execution of the encrypting operation to the random number dependence determining section 522. Thus, the processing state of the encrypting operation can be changed in dependence on the
20 random numbers with the appropriate stage.

The random number dependence determining section 522 determines whether or not the delay time determinating request should be outputted to the delay control section 523, based on the
25 encrypting operation state data from the encrypting operation section 521. The random number dependence determining section 522 outputs

00553415-1042000

the delay time determining request to the delay control section 523, when it is determined that the delay time determining request should be outputted, that is, when the current processing
5 stage of the encrypting operation is determined to be the stage to which a random number dependent operation should be applied.

0000240" 57E5560
The delay control unit 523 sends the delay time determining request to the random number
10 generating unit 540, when the delay time determining request is supplied from the random number dependence determining section 522. Then, the delay control unit 523 generates a random number generating request to the random number
15 generating unit 540. The random number generating unit 540 generates the random numbers. Thus, the delay control unit 523 acquires the random numbers. The delay control unit 523 carries out the random number dependent delay inserting
20 operation based on the acquired random numbers. That is, the delay control unit 523 carries out the operation to determine the execution delay time during the encrypting operation and to intentionally insert the determined delay into
25 the encrypting operation.

It should be noted that the delay control unit 523 controls the random number dependence

delay time inserting operation by the encrypting operation section 521 in the encrypting operation. The insertion of the delay time does not influence the data necessary for the encrypting operation. Therefore, the ciphertext finally outputted from the encrypting operation section 521 does not depend on the random numbers outputted from the random numbers generating section 540.

10 The storage unit 530 is composed of an intermediate data storage section 531. The intermediate data storage section 531 stores the intermediate data to be held in the encrypting operation by the encryption processing unit 520.

15 The random number generating unit 540 generates the random numbers in response to the random number generating request from the encryption processing unit 520 to outputs to the encryption processing unit 520.

20 Fig. 6 is a flow chart showing the processing of the encrypting apparatus in the third embodiment. The processing is composed of a step C1 of supplying a plaintext, a step C2 of determining existence or non-existence of the delay time determining request, a step C3 of outputting the random numbers, a step C4 of carrying out the random number dependent delay

25

0000240"5T45560

time inserting operation, a step C5 of carrying
out one encrypting stage of the encrypting
operation, a step C6 of determining the end of
the encrypting operation, and a step C7 of
5 outputting a ciphertext.

Next, the operation of the whole encrypting
apparatus according to the third embodiment will
be described in detail with reference to Fig. 5
and Fig. 6.

10 First, a plaintext which should be
encrypted is supplied from the input unit 510 to
the encrypting operation section 521 in the
encryption processing unit 520 (at a step C1 of
Fig. 6).

15 The encrypting operation section 521
outputs the stage data of the encrypting
operation by the encrypting operation section 521
to the random number dependence determining
section 522 as the stage data at a previous
20 stage.

The random number dependence determining
section 522 determines based on the encrypting
stage data of the encrypting operation, whether
or not the current encrypting stage of the
25 encrypting operation is the stage to insert the
delay time in dependence on the random numbers.
When the current encrypting stage is determined

0000240 515 1042000

to be the stage to insert the delay time in dependence on the random numbers, the random number dependence determining section 522 outputs the delay time determining request to the delay control section 523.

The delay control section 523 determines whether or not the delay time determining request is outputted from the random number dependence determining section 522 (Step C2).

10 The conditional branch control section 523 receives the delay time determining request and sends the delay time determining request to the random number generating unit 540, when it is determined at the step C2 that the delay time
15 determining request is outputted. Also, the delay control section 523 receives the random numbers outputted from the random number generating unit 540 based on the delaytime determining request (Step C3).

20 The conditional branch control section 523 receives the random numbers and carries out the random number dependent delay time determining operation, and then requests the encrypting operation section 521 to intentionally insert the
25 determined delay time in the encrypting operation (Step C4).

The encryption operation section 521

09553415 "042000

executes the encrypting operation for a single stage when the random number dependent delay time determining operation of the step C4 is ended, or when it is determined at the step C2 that the
5 delay time determining request is not outputted (Step C5).

The encrypting operation section 521 determines whether or not the encrypting operation is ended, after the encrypting
10 operation is executed for the single stage (Step C6).

The encrypting operation section 521 outputs a ciphertext to the output unit 550 when it is determined at the step C6 that the
15 encrypting operation is ended (Step C7). In this way, the whole processing ends.

On the other hand, when the encrypting operation section 521 determines at the step C6 that the encrypting operation does not end, the
20 control returns to the step C2 to continue the encrypting operation.

In the third embodiment, the random number dependent delay time is appropriately inserted in the encrypting operation. Therefore, the process
25 time effective for the cryptanalysis is continuously changed. Thus, it is difficult to determine which of the process times is effective

0000240" 5THES560

for the cryptanalysis.. Therefore, the encrypting apparatus has the endurance to the cryptanalysis such as the simple power analysis and the power differential analysis.

5 It should be noted that in the above first to third embodiments, the encrypt key is previously stored in the encrypting operation section (the encrypting operation section 121 in Fig. 1, the encrypting operation section 321 in Fig. 3 and the encrypting operation section 521 in Fig. 5). However, the encrypt key may be supplied to the encrypting operation section from the input unit (input unit 110 in Fig. 1, input unit 310 in Fig. 3 and input unit 510 in Fig. 5),
10 in the encrypting apparatus in the above-mentioned embodiments. In this case, the encrypting operation section is supplied with the encrypt key and encrypts one or more plaintexts supplied thereto using the encrypt key and
15 outputs one or more ciphertexts. In the above structure, because the encrypt key can be supplied from outside, the encrypt key can be easily updated without changing the encrypting operation section itself.

25 Also, in the encrypting apparatus according to the above-mentioned first, second and third embodiments, it is possible to use data (the

09553415-042000

plaintext) itself which is supplied to the encryption processing unit (the encryption processing unit 120 in Fig. 1, the encryption processing unit 320 in Fig. 3 and the encryption processing unit 520 in Fig. 5) from the input unit or a data dependent on the data in place of the random numbers outputted from the random number generating unit (the random number generating unit 140 in Fig. 1, the random number generating unit 340 in Fig. 3 and the random number generating unit 540 in Fig. 5). The reason why the plaintext can be used as the "random numbers" and is effective in this way is that a cryptanalysis method proposed at present such as the simple power analysis and the power differential analysis is carried out based on the ciphertext and the power consumption. The plaintext is not used for the cryptanalysis method. Therefore, the plaintext can be used in place of the random numbers. It should be noted that the fact that "the data dependent on the plaintext" is used in place of the random numbers contains that the plaintext supplied from the input unit is encrypted by use of "another random number output key" in place of the encrypt key and the encrypting result is used in place of the random numbers. Such an encrypting apparatus

09553415-042000

using the output of the encryption of the plaintext is contained in the present invention.

(4) Fourth embodiment

5 Fig. 7 is a block diagram showing the structure of the encrypting apparatus according to the fourth embodiment of the present invention.

Referring to Fig. 7, the encrypting
10 apparatus in the fourth embodiment is different from that of the first embodiment shown in Fig. 1 in the point that a recording medium 700 is provided to store a program for the encrypting operation by the encrypting apparatus. The
15 recording medium 700 may be a magnetic disk, a semiconductor memory, CD-ROM (Compact Disk-Read Only Memory), or other recording media.

The encrypting operation program is read from the recording medium 700 into a computer
20 system. The computer system is controlled based on the encrypting operation program to realize the input unit 110, the encryption processing unit 120 (the encrypting operation section 121, the random number dependence determining section
25 122 and the intermediate data control section 123), the storage unit 130 (the intermediate data storage section 131), the random number

0000240" STESSD 09553415" 042000

generating unit 140 and the output unit 150. The operations of the input unit 110, encryption processing unit 120, storage unit 130, random number generating unit 140 and output unit 150
5 are the same as those of the first embodiment. Therefore, the detailed description is omitted.

(5) Fifth embodiment

Fig. 8 is a block diagram showing the
10 structure of the encrypting apparatus according to the fifth embodiment of the present invention.

Referring to Fig. 8, the encrypting apparatus in the fifth embodiment is different from that of the first embodiment shown in Fig. 3
15 in the point that a recording medium 800 is provided to store a program for the encrypting operation by the encrypting apparatus. The recording medium 800 may be a magnetic disk, a semiconductor memory, CD-ROM (Compact Disk-Read
20 Only Memory), or other recording media.

The encrypting operation program is read from the recording medium 800 into a computer system. The computer system is controlled based on the encrypting operation program to realize
25 the input unit 310, the encryption processing unit 320 (the encrypting operation section 321, the random number dependence determining section

09553415-042000

10

Fig. 9 is a block diagram showing the structure of the encrypting apparatus according to the sixth embodiment of the present invention.

20

25

15 (7) Seventh embodiment

Referring to Fig. 10, the decrypting apparatus according to the seventh embodiment is composed of an input unit 1010, a decryption processing unit 1020, a storage unit 1030 composed of an intermediate data storage section 1031, a random number generating unit 1040 and an output unit 1050. The decryption processing unit 1020 is composed of a decrypting operation section 1021, a random number dependence

determining section 1022, and an intermediate data control section 1023.

000240" 5TFE5560

The decrypting apparatus according to the seventh embodiment is composed of the input unit, the decryption processing unit, the storage unit, the random number generating unit and the output unit, as in the encrypting apparatus according to the first embodiment. In the first embodiment, a plaintext is supplied from the input unit 110, the encryption processing unit 120 encrypts the plaintext using an encrypt key and a ciphertext is output from the output unit 150. On the other hand, in the seventh embodiment, a ciphertext is supplied from the input unit 1010, the decryption processing unit 1020 carries out the decryption of the ciphertext using a decrypt key stored in the decryption processing unit 1020 and a plaintext is outputted from the output unit 1050.

The decrypting operation in the seventh embodiment is an inverse operation of the encrypting operation in the first embodiment. Therefore, the decrypting operation can be read by exchanging the plaintext and the ciphertext in the flow chart of Fig. 2. The structure and operations other than the above point are the same as those of the first embodiment.

(8) Eighth embodiment

Fig. 11 is a block diagram showing the structure of the decrypting apparatus according to the eighth embodiment of the present invention.

Referring to Fig. 11, the decrypting apparatus according to the eighth embodiment is composed of an input unit 1110, a decryption processing unit 1120, a storage unit 1130 composed of an intermediate data storage section 1131, a random number generating unit 1140 and an output unit 1150. The decryption processing unit 1120 is composed of a decrypting operation section 1121, a random number dependence determining section 1122, and an conditional branch control section 1123.

The decrypt apparatus according to the eighth embodiment is composed of the input unit, the decryption processing unit, the storage unit, the random number generating unit and the output unit, as in the encrypting apparatus according to the second embodiment. In the second embodiment, a plaintext is supplied from the input unit 310, the encryption processing unit 320 encrypts the plaintext using an encrypt key and a ciphertext is output from the output unit 350. On the other hand, in the eighth embodiment, a ciphertext is

000240" 5T4E560

supplied from the input unit 1110, the decryption processing unit 1120 carries out the decryption of the ciphertext using a decrypt key stored in the decryption processing unit 1120 and a
5 plaintext is outputted from the output unit 1150.

The decrypting operation in the eighth embodiment is an inverse operation of the encrypting operation in the second embodiment. Therefore, the decrypting operation can be read
10 by exchanging the plaintext and the ciphertext in the flow chart of Fig. 4. The structure and the operations other than the above point are the same as those of the second embodiment.

15 (9) Ninth embodiment

Fig. 12 is a block diagram showing the structure of the decrypting apparatus according to the ninth embodiment of the present invention.

Referring to Fig. 12, the decrypting
20 apparatus according to the ninth embodiment is composed of an input unit 1210, a decryption processing unit 1220, a storage unit 1230 composed of an intermediate data storage section 1231, a random number generating unit 1240 and an
25 output unit 1250. The decryption processing unit 1220 is composed of a decrypting operation section 1221, a random number dependence

000240-5755560

determining section 1222, and a delay control section 1223.

09553415 "042000

The decrypt apparatus according to the ninth embodiment is composed of the input unit, the decryption processing unit, the storage unit, the random number generating unit and the output unit as in the encrypting apparatus according to the third embodiment. In the third embodiment, a plaintext is supplied from the input unit 510, the encryption processing unit 520 encrypts the plaintext using an encrypt key and a ciphertext is output from the output unit 550. On the other hand, in the ninth embodiment, a ciphertext is supplied from the input unit 1210, the decryption processing unit 1220 carries out the decryption of the ciphertext using a decrypt key stored in the decryption processing unit 1120 and a plaintext is outputted from the output unit 1250.

The decrypting operation in the ninth embodiment is an inverse operation of the encrypting operation in the third embodiment. Therefore, the decrypting operation can be read by exchanging the plaintext and the ciphertext in the flow chart of Fig. 6. The structure and the operations other than the above point are the same as those of the third embodiment.

It should be noted that in the decrypting

apparatus according to the above-mentioned seventh, eighth and ninth embodiments, the decrypt key may be supplied from the input unit (the input unit 1010 in Fig. 10, the input unit 1110 in Fig. 11 or the input unit 1210 in Fig. 12) to the decrypting operation section (decrypting operation section 1021 in Fig. 10, decrypting operation section 1121 in Fig. 11 or decrypting operation section 1221 in Fig. 12).

Also, in the decrypting apparatus according to the above-mentioned seventh, eighth and ninth embodiments, it is possible to use a data (the ciphertext) itself supplied to the decryption processing unit (decryption processing unit 1020 in Fig. 10, decryption processing unit 1120 in Fig. 11 or decryption processing unit 1220 in Fig. 12) from the input unit or a data dependent on the data for the decrypting operation in place of the random numbers outputted from the random number generating unit (the random number generating unit 1040 in Fig. 10, the random number generating unit 1140 in Fig. 11 or the random number generating unit 1240 in Fig. 12).

(10) Tenth embodiment

Fig. 13 is a block diagram showing the structure of the decrypting apparatus according

000240" 54E5560

to the tenth embodiment of the present invention.

Referring to Fig. 13, the decrypting apparatus in the tenth embodiment is different from that of the seventh embodiment shown in Fig. 10 in the point that a recording medium 1300 is provided to store a program for the decrypting process by the decrypting apparatus. The recording medium 1300 may be a magnetic disk, a semiconductor memory, a CD-ROM (Compact Disk-Read Only Memory), or other recording media.

The decrypting operation program is read from the recording medium 1300 into the computer system. The computer system is controlled based on the decrypting operation program to realize the input unit 1010, the encryption processing unit 1020 (the encrypting operation section 1021, the random number dependence determining section 1022 and the intermediate data control section 1023), the storage unit 1030 (the intermediate data storage section 1031), the random number generating unit 1040 and the output unit 1050. The operations of the input unit 1010, encryption processing unit 1020, storage unit 1030, random number generating unit 1040 and output unit 1050 are the same as those of the seventh embodiment. Therefore, the detailed description is omitted.

0000240" 514E5560

(11) Eleventh embodiment

Fig. 14 is a block diagram showing the structure of the decrypting apparatus according to the eleventh embodiment of the present invention.

Referring to Fig. 14, the decrypting apparatus in the eleventh embodiment is different from that of the eighth embodiment shown in Fig. 11 in the point that a recording medium 1400 is provided to store a program for the decrypting operation by the decrypting apparatus. The recording medium 1400 may be a magnetic disk, a semiconductor memory, CD-ROM (Compact Disk-Read Only Memory), or the other recording media.

The decrypting operation program is read from the recording medium 1400 into a computer system. The computer system is controlled based on the decrypting operation program to realize the input unit 1110, the encryption processing unit 1120 (the encrypting operation section 1121, the random number dependence determining section 1122 and the conditional branch control section 1123), the storage unit 1130 (the intermediate data storage section 1131), the random number generating unit 1140 and the output unit 1150. The operations of the input unit 1110, encryption processing unit 1120, storage unit 1130, random

09553415-042000

number generating unit 1140 and output unit 1150 are the same as those of the eighth embodiment. Therefore, the detailed description is omitted.

5 (12) Twelveth embodiment

Fig. 15 is a block diagram showing the structure of the encrypting apparatus according to the twelveth embodiment of the present invention.

10 Referring to Fig. 15, the decrypting apparatus in the twelveth embodiment is different from that of the ninth embodiment shown in Fig. 12 in the point that a recording medium 1500 is provided to store a program for the decrypting
15 operation by the decrypting apparatus. The recording medium 1500 may be a magnetic disk, a semiconductor memory, CD-ROM (Compact Disk-Read Only Memory), or other recording media.

The decrypting operation program is read
20 from the recording medium 1500 into a computer system. The computer system is controlled based on the decrypting operation program to realize the input unit 1210, the encryption processing unit 1220 (the encrypting operation section 1221,
25 the random number dependence determining section 1222 and the delay control section 1223), the storage unit 1230 (the intermediate data storage

00553415.042000

section 1231), the random number generating unit 1240 and the output unit 1250. The operations of the input unit 1210, encryption processing unit 1220, storage unit 1230, random number generating
5 unit 1240 and output unit 1250 are the same as those of the ninth embodiment. Therefore, the detailed description is omitted.

(13) Thirteenth embodiment

10 Fig. 16 is a block diagram showing the structure of an encrypting and decrypting apparatus according to the thirteenth embodiment of the present invention.

Referring to Fig. 16, the encrypting and
15 decrypting apparatus according to the thirteen embodiment is composed of an input unit 1610, an encryption and decryption processing unit 1620, a storage unit 1630 composed of an intermediate data storage section 1631, a random number
20 generating unit 1640 and an output unit 1050. The encryption and decryption processing unit 1620 is composed of an encrypting and decrypting operation section 1621, a random number dependence determining section 1622, and an
25 intermediate data control section 1623.

The encrypting and decrypting apparatus according to the thirteenth embodiment has the

000210" STESSD
0953415-042000

function of the encrypting apparatus according to the first embodiment and the decrypting apparatus according to the seventh embodiment. The input unit 1610, the random number dependence

5 determining section 1622, the intermediate data control section 1623, the storage unit 1630, the random number generating unit 1640, and the output unit 1650 are the same as those having the same names in the first embodiment and the
10 seventh embodiment.

The encrypting and decrypting operation section 1621 receives a first plaintext or a second ciphertext together with an encrypt instruction or a decrypt instruction from the
15 input unit 1610. The encrypting and decrypting operation section 1621 carries out the encrypting operation to the first plaintext in response to the encrypt instruction while changing the encrypting states based on the random number
20 dependent intermediate data changing operation from the intermediate data control section 1623. Also, the encrypting and decrypting operation section 1621 carries out the decrypting process to the first cipher text in response to the
25 decrypt instruction while changing the decrypting states based on the random number dependent intermediate data changing operation from the

09553415.042000

intermediate data control section 1623. The
encrypting and decrypting operation section 1621
encrypts the first plaintext into a first
ciphertext, which does not depend on the output
5 of the random number generating unit 1640, and
outputs the first ciphertext from the output unit
1650. Also, the encrypting and decrypting
operation section 1621 decrypts the second
ciphertext into a second plaintext, which does
10 not depend on the output of the random number
generating unit 1640, and outputs the second
plaintext from the output unit 1650.

(14) Fourteenth embodiment

15 Fig. 17 is a block diagram showing the
structure of an encrypting and decrypting
apparatus according to the fourteenth embodiment
of the present invention.

Referring to Fig. 17, the encrypting and
20 decrypting apparatus according to the fourteenth
embodiment is composed of an input unit 1710, an
encryption and decryption processing unit 1720, a
storage unit 1730 composed of an intermediate
data storage section 1731, a random number
25 generating unit 1740 and an output unit 1750. The
encryption and decryption processing unit 1720 is
composed of an encrypting and decrypting

0000240" 545560

operation section 1721, a random number dependence determining section 1722, and a conditional branch control section 1723.

The encrypting and decrypting apparatus according to the fourteenth embodiment has the function of the encrypting apparatus according to the second embodiment and the function of the decrypting apparatus according to the eighth embodiment. The input unit 1710, the random number dependence determining section 1722, the intermediate data control section 1723, the storage unit 1730, the random number generating unit 1740, and the output unit 1750 are the same as those having the those in the second embodiment and the eighth embodiment.

The encrypting and decrypting operation section 1721 receives a first plaintext or a second ciphertext together with an encrypt instruction or a decrypt instruction from the input unit 1710. The encrypting and decrypting operation section 1721 carries out the encrypting operation to the first plaintext in response to the encrypt instruction while changing the encrypting state based on the random number dependent conditional branch determining operation by the conditional branch control section 1723. Also, the encrypting and decrypting

0000240"STHES50

operation section 1721 carries out the decrypting process to the first cipher text in response to the decrypt instruction while changing the decrypting states based on the random number
5 dependent conditional branch determining operation by the conditional branch control section 1723. The encrypting and decrypting operation section 1721 encrypts the first plaintext into a first ciphertext which does not
10 depend on the output of the random number generating unit 1740, and outputs the first ciphertext from the output unit 1750. Also, the encrypting and decrypting operation section 1721 decrypts the second ciphertext into a second
15 plaintext, which does not depend on the output of the random number generating unit 1740, and outputs the second plaintext from the output unit 1750.

20 (15) Fifteenth embodiment

Fig. 18 is a block diagram showing the structure of an encrypting and decrypting apparatus according to the fifteenth embodiment of the present invention.

25 Referring to Fig. 18, the encrypting and decrypting apparatus according to the fifteenth embodiment is composed of an input unit 1810, an

09553415-042000

encryption and decryption processing unit 1820, a storage unit 1830 composed of an intermediate data storage section 1831, a random number generating unit 1840 and an output unit 1750. The
5 encryption and decryption processing unit 1820 is composed of an encrypting and decrypting operation section 1821, a random number dependence determining section 1822, and a delay control section 1823.

10 The encrypting and decrypting apparatus according to the fifteenth embodiment has the function of the encrypting apparatus according to the third embodiment and the function of the decrypting apparatus according to the ninth
15 embodiment. The input unit 1810, the random number dependence determining section 1822, the delay control section 1823, the storage unit 1830, the random number generating unit 1840, and the output unit 1850 are the same as those in the
20 third embodiment and the ninth embodiment.

 The encrypting and decrypting operation section 1821 receives a first plaintext or a second ciphertext together with an encrypt instruction or a decrypt instruction from the
25 input unit 1810. The encrypting and decrypting operation section 1821 carries out the encrypting operation to the first plaintext in response to

0000240"SF4E560

the encrypt instruction while changing the
encrypting state based on the random number
dependent delay inserting operation by the delay
control section 1823. Also, the encrypting and
5 decrypting operation section 1821 carries out the
decrypting process to the first cipher text in
response to the decrypt instruction while
changing the decrypting states based on the
random number dependent delay inserting operation
10 by the delay control section 1823. The encrypting
and decrypting operation section 1821 encrypts the
first plaintext into a first ciphertext which
does not depend on the output of the random
number generating unit 1840, and outputs the
15 first ciphertext from the output unit 1850. Also,
the encrypting and decrypting operation section
1821 decrypts the second ciphertext into a second
plaintext, which does not depend on the output of
the random number generating unit 1840, and
20 outputs the second plaintext from the output unit
1850.

It should be noted that in the encrypting
and decrypting apparatus according to the above-
mentioned thirteenth, fourteenth and fifteenth
25 embodiments, an encrypt key and a decrypt key may
be supplied from the input unit (input unit 1610
in Fig. 16, input unit 1710 in Fig. 17 or input

0000240"0420000

5

10

20

(16) Sixteenth embodiment

Fig. 19 is a block diagram showing the

structure of the encrypting and decrypting apparatus according to the sixteenth embodiment of the present invention.

Referring to Fig. 19, the encrypting and
5 decrypting apparatus in the sixteenth embodiment is different from that of the thirteenth embodiment shown in Fig. 16 in the point that a recording medium 1900 is provided to store a program for the encrypting and decrypting
10 operation by the encrypting and decrypting apparatus. The recording medium 1900 may be a magnetic disk, a semiconductor memory, a CD-ROM (Compact Disk-Read Only Memory), or other recording media.

15 The encrypting and decrypting operation program is read from the recording medium 1900 into a computer system. The computer system is controlled based on the encrypting and decrypting operation program to realize the input unit 1610,
20 the encryption and decryption processing unit 1620 (the encrypting and decrypting operation section 1621, the random number dependence determining section 1622 and the intermediate data control section 1623), the storage unit 1630
25 (the intermediate data storage section 1631), the random number generating unit 1640 and the output unit 1650. The operations of the input unit 1610,

09553415-042000

encryption and decryption processing unit 1620, storage unit 1630, random number generating unit 1640 and output unit 1650 are the same as those of the thirteenth embodiment. Therefore, the
5 detailed description is omitted.

(17) Seventeenth embodiment

Fig. 20 is a block diagram showing the structure of the encrypting and decrypting
10 apparatus according to the seventeenth embodiment of the present invention.

Referring to Fig. 20, the encrypting and decrypting apparatus in the seventeenth embodiment is different from that of the
15 fourteenth embodiment shown in Fig. 17 in the point that a recording medium 2000 is provided to store a program for the encrypting and decrypting operation by the encrypting and decrypting apparatus. The recording medium 2000 may be a
20 magnetic disk, a semiconductor memory, a CD-ROM (Compact Disk-Read Only Memory), or other recording media.

The encrypting and decrypting operation program is read from the recording medium 2000
25 into a computer system. The computer system is controlled based on the encrypting and decrypting operation program to realize the input unit 1710,

00553415 042000

the encryption and decryption processing unit
1720 (the encrypting and decrypting operation
section 1721, the random number dependence
determining section 1722 and the conditional
5 branch control section 1723), the storage unit
1730 (the intermediate data storage section
1731), the random number generating unit 1740 and
the output unit 1750. The operations of the input
unit 1710, encryption and decryption processing
10 unit 1720, storage unit 1730, random number
generating unit 1740 and output unit 1750 are the
same as those of the fourteenth embodiment.
Therefore, the detailed description is omitted.

15 (18) Eighteenth embodiment

Fig. 21 is a block diagram showing the
structure of the encrypting and decrypting
apparatus according to the eighteenth embodiment
of the present invention.

20 Referring to Fig. 21, the encrypting and
decrypting apparatus in the eighteenth embodiment
is different from that of the fifteenth
embodiment shown in Fig. 18 in the point that a
recording medium 2100 is provided to store a
25 program for the encrypting and decrypting
operation by the encrypting and decrypting
apparatus. The recording medium 2100 may be a

0000240" STESS60

magnetic disk, a semiconductor memory, a CD-ROM (Compact Disk-Read Only Memory), or other recording media. recording medium.

The encrypting and decrypting operation
5 program is read from the recording medium 2100
into a computer system. The computer system is
controlled based on the encrypting and decrypting
operation program to realize the input unit 1810,
the encryption and decryption processing unit
10 1820 (the encrypting and decrypting operation
section 1821, the random number dependence
determining section 1822 and the delay control
section 1823), the storage unit 1830 (the
intermediate data storage section 1831), the
15 random number generating unit 1840 and the output
unit 1850. The operations of the input unit 1810,
encryption and decryption processing unit 1820,
storage unit 1830, random number generating unit
1840 and output unit 1850 are the same as those
20 of the fifteenth embodiment. Therefore, the
detailed description is omitted.

First Specific Example of Encrypting Operation

Fig. 22 and Fig. 23 are diagrams to
25 describe a first specific example of the
encrypting apparatus of the present invention. In
the encrypting apparatus according to the above-

0953415-042000

mentioned first specific example, a common key cipher DES (Data Encryption Standard) is used. It should be noted that the DES cipher is described in "Handbook of Applied Cryptography" by A.

- 5 Menezes, P. Oorschot, and S. Vanstone (CRC Press, 1997, ISBN 0-8493-8523-7, pp.250-259).

Here, the outline of the structure and operation of the DES is first shown using Fig. 22.

10 DES is composed of a key scheduling section 2210 and a data processing section 2220. The key scheduling section 2210 receives a 64-bit encrypt key and outputs 16 48-bit intermediate keys K_1 to K_{16} . The data processing section 2220 is composed
15 of an initial translocation IP , the last translocation IP^{-1} and 16 F functions. The data processing section 2220 receives a 64-bit plaintext and the 16 48-bit intermediate keys K_1 to K_{16} from the key scheduling section 2210 and
20 outputs a 64-bit ciphertext. Here, the IP translocation and the IP^{-1} translocation are the functions to rearrange the previously set bits. The 16 F function is a predetermined function to receive a 32-bit data and a 48-bit data to output
25 a 32-bit data.

The encryption of the plaintext into the ciphertext is carried out as follows.

000024015-042000

First, an initial translocation IP is applied to a plaintext. Then, the plaintext is divided into an upper 32-bit set L0 and a lower 32-bit set R0. Subsequently, L₁, R₁, L₂, R₂, L₃,
5 R₃, ..., L₁₅, R₁₅, L₁₆, and R₁₆ are generated in accordance with the following equation (1) from these sets of L0 and R0.

$$L_n = R_{n-1}$$

$$R_n = L_{n-1} \oplus F(R_{n-1}, K_n) \quad (1)$$

10 where n = 1, 2, ..., 16, and the symbol F in the above equation is the F function of the DES.

It should be noted that the above-mentioned L₀, R₀, L₁, R₁, ... correspond to the intermediate data stored in the intermediate data storage
15 section 131 in Fig. 1.

The 16 F functions of the DES have the same structure. Each of the 16 F functions receives a 32-bit data R_{n-1} and the 48-bit intermediate key K_n from the key scheduling section 2210 and outputs
20 the 32-bit data. The above equation (1) is applied 16 times and the sets L₁₆ and R₁₆ are determined at that time. The last translocation IP⁻¹ is applied to the 64-bit data having the set of L₁₆ as the upper 32 bits and the set of R₁₆ as
25 the lower 32 bits. Thus, a 64-bit ciphertext is obtained.

The concept of this embodiment is shown in

0000240" 0420000 09553415

Fig. 23. Referring to Fig. 23, portions (2310 to 2380 in Fig. 23) which are surrounded by the broken lines in Fig. 23 are portions to give the intermediate data a random number dependent change which is necessary in the encrypting operation of the DES. That is, the random number dependent change portion indicates the random number dependent intermediate data changing operation which is carried out by the intermediate data control section 123 in Fig. 1.

Below, the structure and operation of this specific example of the encrypting apparatus will be described with reference to Fig. 22 and Fig. 23.

First, a plaintext is supplied from an IC card reader and writer as the input unit. The plaintext is divided into a set of upper 32 bits and a set of lower 32 bits after the initial translocation IP is carried out. At this time, the intermediate data control section 123 is called.

The intermediate data control section receives two random numbers r_0 and r_1 from the random number generating unit 140. The intermediate data control section 123 calculates the exclusive OR of the set of upper 32-bit data and the random numbers r_0 and stores the

0000240"STAES560

calculation result in L_0 (see 2310 in Fig. 23).
Also, the intermediate data control section 123
calculates the exclusive OR of the set of lower
32-bit data and the random numbers r_1 and stores
5 the calculation result in R_0 (see 2320 in Fig.
23).

Next, the following operation is repeated
in case of $n = 1, 2, \dots, 16$.

$$r^* = \begin{cases} r_1 & n=1,4,7,10,13,16 \\ r_0 \oplus r_1 & n=2,5,8,11,14 \\ r_0 & n=3,6,9,12,15 \end{cases}$$

Here, the value of r^* is defined as follows.

10 First, the value of R_{n-1} is copied to L_n .
Then, the intermediate data control section 123
is called again and calculates the exclusive OR
of R_{n-1} and r^* (see 2340, 2360 and 2380 of Fig.
23). The calculation result of the exclusive OR
15 value and K_n are supplied to the F function.
Through the above procedure, R_{n-1} and K_n are
supplied to the F function, and therefore, it is
ascertained that it does not depend on the random
numbers r^* which is outputted from the random
20 number generating unit 140.

When a value of F function is outputted,
the intermediate data control section 123 is
called and the exclusive OR of output of the F
function output and the random numbers of r^* is

0000240"574E5560

again calculated (see 2330, 2350 and 2370 of Fig. 23). Moreover, the exclusive OR of the calculation result of the exclusive OR and L_{n-1} is calculated and the calculation result is stored
5 in L_n .

The above operation is repeated 16 times. Thus, a 64-bit data is obtained to have the calculation result of the exclusive OR of L_{16} and r_1 as the set of upper 32 bits and the calculation
10 result of the exclusive OR of R_{16} , r_0 and r_1 as a set of lower 32 bits. The 64-bit data is subjected to the last translocation IP^{-1} and then is outputted through the IC card reader and writer as a ciphertext. The ciphertext does not
15 depend on any of the random numbers r_0 and r_1 operated to the intermediate data, the random numbers for controlling a delay time and the random numbers for determining the execution sequence of S-box.

20

Second Specific Example of Encrypting Operation

Fig. 24, Fig. 25 and Fig. 26 are diagrams to explain the second specific example of the encrypting apparatus of the present invention. In
25 the second specific example of the encrypting apparatus, the common key cipher RC5-32/12/16 is applied to the encrypting apparatus according to,

00002415 "0420000

for example, the above-mentioned second embodiment. The details of the algorithm of RC5-32/12/16 is described in "Handbook of Applied Cryptography" (pp.269-270) mentioned above.

5 Here, first, the outline of the operation of RC5-32/12/16 will be described with reference to Fig. 24 and Fig. 25.

RC5-32/12/16 is the algorithm which converts a 64-bit plaintext 2410 into a 64-bit
10 ciphertext 2450 using 128-bit encrypt key 2420 as shown in Fig. 24. RC5-32/12/16 has a data processing section 2430 and an extended key generating section 2440.

The extended key generating section 2440
15 receives the 128-bit encrypt key 2420 and outputs 26 32-bit extended keys S_0, S_1, \dots, S_{25} .

The data processing section 2430 receives the 64-bit plaintext 2410, and the outputs S_0, S_1, \dots, S_{25} of the extended key generating section
20 2440, and outputs the 64-bit ciphertext 2450.

The data processing section 2430 operates as follows.

First, the 64-bit plaintext 2410 supplied thereto is divided into a set of upper 32 bits A
25 and a set of lower 32 bits B. Next, the summation (the addition) of A and S_0 modulo 2^{32} is calculated and the calculation result is again substituted

0000210" 5TFESS60

for A (see 2431 of Fig. 24). Also, the summation
of B and S_1 modulo 2^{32} is calculated and the
calculation result is again substituted for B
(see 2432 of Fig. 24). After that, the conversion
5 using a round function is applied to A and B 12
times. The ciphertext 2450 is a 64-bit data
having A after applying the round function 12
times as a set of upper 32 bits and B after
applying the round function 12 times as a set of
10 lower 32 bits.

When the round function is applied for the
i-th time, data of A and B are updated using A,
B, S_{2i} and S_{2i+1} and the updated data of A and B
are outputted.

15 Next, an outline of the round function
which is applied for the i-th time will be
described. the update of A and B using the round
function applied for the i-th time is carried out
in accordance with the following equation.

$$A = ((A \oplus B) \lll B) + S_{2i}$$

$$B = ((B \oplus A) \lll A) + S_{2i+1}$$

20 where, the symbol " \oplus " indicates the summation
using modulo 2^{32} and the symbol " $X \lll Y$ " indicates
Y-bit rotation of X.

Referring to Fig. 25, the updating of A is
first carried out. The exclusive OR 2510 of A and
25 B is calculated for every bit and the calculation

0000240"ST4ES560

result of the exclusive OR is again stored in A.

Next, A is subjected to a left direction rotation 2520 for B bits and the rotation result is stored in A again. Last, the summation 2530 of
5 A and the extended key S_{21} modulo 2^{32} is calculated and the calculation result is set as the value of A after the update.

Next, the updating of B is carried out. The exclusive OR 2540 of A after the update and B
10 is calculated for every bit and the calculation result of the exclusive OR is again stored in B.

Next, B is subjected to a left direction rotation 2550 for A bits and the rotation result is stored in B again. Last, the summation 2560 of
15 B and the extended key S_{21+1} modulo 2^{32} is calculated and the calculation result is set as the value of B after the update.

In this embodiment, the encrypting apparatus is composed of the IC card reader and
20 writer as the input unit and the output unit, a semiconductor memory as the data storage unit, a recording medium for storing a program and a computer system provided in an IC card as the encryption processing unit. The computer system
25 for realizing the encryption processing unit has five or more general purpose registers, and instruction sets of the computer system such as a

0000240"545560

5

10

25

to detect whether the change of the measured consumption power is based on the change of the value of the general register R_1 or based on the change of the value of the general register R_j .

5 Next, the operation of this embodiment will be described below in detail.

In this embodiment, first, a plaintext is stored in the encryption processing unit through the input unit (The step D1 of Fig. 26).

10 When the plaintext is supplied to the encryption processing unit, the encryption processing unit calculates addition (the summation using modulo 2^{32}) 2431 and then stores the value of A after the calculation in the
15 general register R_1 . Also, the encryption processing unit calculates addition (the summation using modulo 2^{32}) 2432 and then stores the value of B after the calculation in the
20 general register R_j . Also, the encryption processing unit stores 1 in a variable r which counts the number of times of execution of a round function (Step D2).

25 Next, the encryption processing unit carries out the operation corresponding to 2510 and 2520 of the round function shown in Fig. 25 and then stores S_{2r} in the general register R_2 . At this time point, the conditional branch control

09553415-0420000

5

10

20

When the processing of step D5 is ended,
the processing of the round function ends for

0 Otherwise, the encrypting operation section
returns to the step D3 to add 1 to the variable r
(step D8) and to carry out the round function
once more.

Moreover, the encryption processing unit
25 stores the value of S_{2r+1} in the register R_4 and
stores the summation between the registers R_3 and
 R_4 in the register R_4 . Through the above

operation, the value of A and B after the application of the round function is stored in the registers R2 and R4, respectively (Step D6).

Next, like the step D7, it is checked
5 whether or not the value of r is equal to 12.

When the value of r is equal to 12, the encrypting operation section outputs a ciphertext from the output unit and ends the encrypting operation (Step D16). Otherwise, the encrypting
10 operation section returns to the step D10 to add 1 to the variable r (step D15) and to carry out the round function once more.

In step D10, the values of A and B for the round function are stored in the registers R₂ and
15 R₄, respectively. The encryption processing unit carries out the operations corresponding to the exclusive OR calculation 2510 and the left direction bit rotation 2520 of the round function shown in Fig. 25 and then stores S_{2r} in the
20 general register R1. At this time point, the conditional branch control unit is called. The conditional branch control unit controls the calculation result of summation (the summation using modulo 2^{32}) 2530 of the value of S_{2r} stored
25 in the register R₁ and the value of A stored in the register R₂ to be stored in either of R1 and R2 based on whether the random numbers is an even

0000240"STHES50

number or an odd number (Steps D10 and D11).

When the random numbers is an odd number in the step D11, the calculation result of the summation of the registers R_2 and R_1 is stored in the register R_1 . Subsequently, the encryption processing unit carries out the calculation of the exclusive OR 2540 in the round function and the left direction bit rotation 2550 and stores the value of B in the register R_4 when the left direction bit rotation 2550 is ended. Moreover, the encryption processing unit stores the value of S_{2r+1} in the register R_3 and stores a summation between the registers R_3 and R_4 in the register $R3$. Through the above operation, the values of A and B after the application of the round function are stored in R_1 and R_3 , respectively (Step D12).

When the processing of step D12 is ended, the processing of the round function ends for this time. At this time, the value of the variable r showing the number of times of execution of the round function by the encryption processing unit is checked (Step D7). When the value of r is equal to 12 which is the number of times of the round function to be executed in RC5-32/12/16, the encrypting operation section outputs a ciphertext from the output unit and ends the encrypting operation (Step D9).

0000240.5742560

Otherwise, the encrypting operation section returns to the step D3 to add 1 to the variable r (step D8) and to carry out the round function once more.

5 When the random numbers is an even number in the step D11, the calculation result of the summation of the registers R_2 and R_1 is stored in the register R_2 . Subsequently, the encryption processing unit carries out the calculation of
10 the exclusive OR 2540 in the round function and the left direction bit rotation 2550 and stores the value of B in the register R_4 when the left direction bit rotation 2550 is ended. Moreover, the encryption processing unit stores the value
15 of S_{2r+1} in the register R_3 , and stores the summation between the registers R_3 and R_4 in the register R_4 . Through the above operation, the values of A and B after the application of the round function are stored in the registers R_2 and
20 R_4 , respectively (Step D13).

Next, like the step D7, it is checked whether or not the value of r is equal to 12 (step D14). When the value of r is equal to 12, the encrypting operation section outputs a
25 ciphertext from the output unit and ends the encrypting operation (Step D16). Otherwise, the encrypting operation section returns to the step

000240"STE5560

D10 to add 1 to the variable r (step D15) and to carry out the round function once more.

Through the above-mentioned algorithm, the ciphertext corresponding to the plaintext is
5 outputted to the output unit without depending on the value of the random numbers outputted from the random number generating unit.

Third Specific Example of Encrypting Operation

10 Fig. 27 and Fig. 28 are diagrams to explain the third embodiment of the present invention. In this embodiment, a public key encryption RSA is applied to the encrypting and decrypting apparatus according to the above-mentioned
15 fifteenth embodiment. It should be noted that the algorithm of RSA is described in the above-mentioned "Handbook of Applied Cryptography" (pp.285-291).

Here, first, the outline of the operation
20 of RSA will be described.

RSA has a set (n, e) of a product n of two prime numbers p and q of about 512 bits and a number e in relation of prime number with $\text{lcm}(p-1, q-1)$ ($\text{lcm}(a, b)$ indicates the least common
25 multiple of a and b) as a public key and d to meet $ed=1$ under method $\text{lcm}(p-1, q-1)$ as a secret key.

0000240"STH5560

Supposing that M is a plaintext to be encrypted, a ciphertext C obtained by encrypting M is calculated in accordance with the following equation.

Also, the calculation to decrypt the ciphertext C into the plaintext M is shown by the following equation.

In order to carry out an encryption and decrypting operation at high speed, RSA requires a high speed power surplus calculation algorithm. Here, the power surplus calculation algorithm means the algorithm which receives g , e , and n and outputs $g^e \bmod n$.

In the power surplus calculation algorithm, first, g , e , and n are supplied (step E1 of Fig.

27)). Subsequently l and g are stored in variables A and S as the initial values, respectively (Step E2)).

Next, it is determined whether or not e is
5 0 (Step E3). In case of $e=0$, A is outputted and
the processing is ended. Otherwise, it is
determined whether e is an odd number or an even
number. When e is the odd number, a product of A
and S is calculated and then is stored in A again
10 (Steps E4 and E5).

Next, by dividing the value of e by 2, the
right direction shift of e by one bit is carried
out (Step E6). At this time, it is determined
again whether or not e is 0 (step E7). In case of
15 $e=0$, A is outputted and the processing is ended.
Otherwise, a square of S is calculated (step E8)
and then the processing returns to the step E3.

It is supposed that the binary expression
of e is (b_1, b_2, \dots, b_t) . Here, the most
20 significant bit is b_1 and the least significant
bit is b_t . In this case, the value of A when the
processing passed through the step E7 i times in
the flow chart of Fig. 27 is $g^{e_i} \bmod n$ to the
number e_i to have the binary expression of $(b_1,$
25 $b_2, \dots, b_i)$.

Based on the structure method of the
algorithm, the number of times which the

00553415 "0420000

5

10

25

The the encryption and decryption
processing unit 2820 in the encrypting and

The encryption and decrypting operation section 2821 is composed of a multiplier 2811 which receives two different numbers a and b and calculates $a \cdot b \bmod n$, a multiplier 2812 which receives a single number a and a modulo n and calculates $a^2 \bmod n$.

The encrypting and decrypting operation section 2821 has two functions of the encryption and the decryption. In case of the encryption, a public key e and n_1 of a counter node and a plaintext M to be transmitted are supplied from the input unit 2810. Then, the operation like the flow chart of Fig. 27 is carried out. As a result, the ciphertext $M^e \bmod n_1$ is calculated and the calculation result is outputted from the output unit 2850. Also, in case of the decryption, the secret key d of the user and the public key n_2 of the user and received ciphertext C from the input unit 2810 and the operation is carried out as shown in the flow chart of Fig. 27 to calculate a plaintext from $C^d \bmod n_2$. The calculation result is outputted from the output

unit 2850.

The operation of the encrypting and decrypting operation section 2821 of the in Fig. 28 is different from the encryption and
5 decrypting operation section 2821 in Fig. 28 in the flow chart of Fig. 2 is in the point that a delay time determining request is outputted from the delay control unit 2823 to the random number dependence determining section 2822 when the
10 processing returns from the step E8 to the step E3 of Fig. 27.

The delay control unit 2823 is composed of a multiplier 28231 and a square operating unit 28232 like the encrypting operation section 2821.
15 When a delay time determining request is outputted from the random number dependence determining section 2822, the delay control unit 2823 sends the random number generating request to the random number generating unit 2840 twice
20 and gets two random numbers r_1 and r_2 .

The delay control unit 2823 receives r_1 and r_2 , and determines whether or not the least significant bit of r_1 is 0. When the LSB is 0, the delay control unit 2823 calculates the square
25 of r_2 for the delay insertion using the square operating unit 28232 and moves the processing to the encrypting and decrypting operation section

0000240"STHES550

2821. On The other hand, when the least
significant bit of r_1 is "1", the delay control
unit 2823 calculates a product of r_1 and r_2 using
the multiplier 28231 for the delay insertion, and
5 then calculate the square of $r_1 \cdot r_2$ as the
calculation result of the multiplier 28231 using
the square arithmetic unit 28232. Then, the delay
control unit 2823 moves the processing to the
encrypting and decrypting operation section 2821
10 again.

As described above, according to the
encrypting apparatus, the decrypting apparatus
and the encrypting and decrypting apparatus of
the present invention, it is difficult to apply
15 the cryptanalysis method such as the simple power
analysis and the power differential analysis for
getting secret information such as the encrypt
key and the decrypt key by measuring the power
consumption of the apparatus when the encryption
20 and/or decryption of the data is carried out.

The reason why the above mentioned effect
can be attained will be described below.

In order that the cryptanalysis such as the
simple power analysis and the power differential
25 analysis succeeds through the measurement of the
power consumption, two conditions are necessary.

That is, the first matter is that there is

00553415 042000

a close relation between the power consumed when the encrypting apparatus and the decrypting apparatus carry out the encryption and decryption of the data and a decrypt, and the encrypting and
5 decrypting operation carried out in the apparatus. The second matter is that it is easy to detect the time when the encrypting apparatus and the decrypting apparatus carry out a specific encrypting and decrypting operation.

10 In the present invention, the encrypting operation and the decrypting operation are carried out in the encrypting apparatus and the decrypting apparatus while the intermediate data which are necessary for the encryption and the
15 decryption are changed in dependence on the random numbers by the intermediate data control section. Therefore, it is difficult to determine whether the change of the power consumption of the apparatus is due to the encrypting operation
20 and the decrypting operation or due to the influence of the random numbers. In this way, it is difficult to detect relation between the consumption power of the encrypting apparatus and the decrypting apparatus, and the encrypting
25 operation and decrypting operation which are carried out in the apparatus. Thus, the first condition for the simple power analysis and the

09553415-042000

power differential analysis is not met.

Moreover, in the present invention, The determination of the execution order of operations which can be replaced and the
5 selection of an actually executed operation from among a plurality of encrypting or decrypting operations which does not influence the encrypting or decrypting result is carried out in dependence on the random numbers by the
10 conditional branch control unit. Also, the delay time is appropriately inserted on the way of the encrypting operation or decrypting operation in dependence on the random numbers by the delay control unit. Therefore, the time that a specific
15 encrypting operation or decrypting operation is executed is changed based on the random numbers. Thus, the second condition for the simple power analysis and the power differential analysis is not met.

20 The above first to third specific examples may be applied to the encrypting operations in the other embodiments, and may be also applied to the decrypting apparatus.

By the above, two conditions necessary for
25 the simple power analysis and the power differential analysis are not met. Therefore, it is difficult to succeed the cryptanalysis method

0000240"STE5560

for secret information by measuring the
consumption power of the encrypting apparatus and
the decrypting apparatus.
